# Special cases of lower previsions and their use in statistics 

I. Couso D. Dubois<br>IRIT-CNRS, Université Paul Sabatier 31062 TOULOUSE FRANCE

## Outline

1. Set-valued representations of ignorance
2. Capacity-based uncertainty theories and their links to imprecise probability
3. Practical representations
4. Statistics with interval data
(From the simplest to the more complex representations of uncertainty)

## Motivation for going beyond probability

- Distinguish between uncertainty due to variability from uncertainty due to lack of knowledge or missing information.
- The main tools to representing uncertainty are
- Probability distributions: good for expressing variability, but information demanding
- Sets: good for representing incomplete information, but often crude representation of uncertainty
- Find representations that allow for both aspects of uncertainty.

## Example

- Variability: daily quantity of rain in Toulouse
- May change every day
- It is objective: can be estimated through statistical data
- Incomplete information : Birth date of Brazilian President
- It is not a variable: it is a constant!
- Information is subjective: Most may have a rough idea (an interval), a few know precisely, some have no idea.
- Statistics on birth dates of other presidents do not help much.

## What do set-valued data mean?

- A set can represent
- the precise description of an actual object (ontic set) : a region in an image.
- or incomplete information about an ill-known entity (epistemic set) : interval containing an ill-known birthdate.
- The ill-known entity can be
- A constant ( $x \in E$ )
- or a random variable $\left(P_{-} x \in\{P: P(E)=1\}\right)$.

## Set-Valued Representations of Partial Knowledge

- An ill-known quantity $x$ is represented as a disjunctive set, i.e. a subset E of mutually exclusive values, one of which is the real one.
- Pieces of information of the form $x \in E$
- Intervals $\mathrm{E}=[\mathrm{a}, \mathrm{b}]$ : good for representing incomplete numerical information
- Classical Logic: good for representing incomplete symbolic (Boolean) information
$\mathrm{E}=$ Models of a wff $\phi$ stated as true.
This kind of information is subjective (epistemic set)

## BOOLEAN POSSIBILITY THEORY

Natural set functions under incomplete information:
If all we know is that $x \in E \neq \emptyset$ then

- Event A is possible if $\mathrm{A} \cap \mathrm{E} \neq \emptyset$ (logical consistency)

$$
\frac{\text { Possibility measure }}{\Pi(\mathrm{A} \cup \mathrm{~B})=\max (\Pi(\mathrm{A}), \Pi(\mathrm{B})) ;} \quad \begin{aligned}
& \Pi(\mathrm{A})=1 \text {, and } 0 \text { otherwise }
\end{aligned}
$$

- Event A is sure if $\mathrm{E} \subseteq \mathrm{A} \quad$ (logical deduction) Necessity measure $\quad \mathrm{N}(\mathrm{A})=1$, and 0 otherwise

$$
\mathrm{N}(\mathrm{~A} \cap \mathrm{~B})=\min (\mathrm{N}(\mathrm{~A}), \mathrm{N}(\mathrm{~B})) .
$$

$$
\begin{gathered}
N(A)=1-\Pi\left(A^{c}\right): N(A)=1 \text { iff } \Pi\left(A^{c}\right)=0 \\
N(A) \leq \Pi(A)
\end{gathered}
$$

This corresponds to a fragment of a modal logic (KD)

## Representations of uncertainty due to incompleteness

- More expressive than epistemic sets (pure intervals or classical logic), and Boolean possibility theory
- Less demanding than single probability distributions
- Explicitly allows for missing information
- Allows for addressing the same problems as probability.

## Possibility Theory

(Shackle, 1961, Zadeh, 1978)

- A piece of incomplete information " $x \in E$ " admits of degrees of possibility: $\mathrm{E} \subseteq \mathrm{S}$ is a (normalized) fuzzy set : $\mu_{\mathrm{E}}: \mathrm{S} \rightarrow[0,1]$
- $\mu_{\mathrm{E}}(\mathrm{s})=\operatorname{Possibility}(\mathrm{x}=\mathrm{s})=\pi_{\mathrm{x}}(\mathrm{s})$ in $[0,1]$
- $\pi_{x}(s)$ is the degree of plausibility of $x=s$
- Conventions: $\pi_{x}(s)=1$ for some value s.
$\pi_{x}(s)=0$ iff $x=s$ is impossible, totally surprising
$\pi_{\mathrm{x}}(\mathrm{s})=1$ iff $\mathrm{x}=\mathrm{s}$ is normal, fully plausible, unsurprising (but no certainty)

## A family of nested epistemic sets

In the continuous case: $\alpha=\operatorname{Poss}\left(x\right.$ not in $A_{\alpha}$ )

FUZZY INTERVAL

## Improving expressivity of incomplete information representations

What about the birth date of the president?

- partial ignorance with ordinal preferences : May have reasons to believe that $1933>1932 \equiv 1934>1931 \equiv 1935$ > $1930>1936>1929$
- Linguistic information described by fuzzy sets:
" he is old ": membership function $\mu_{\text {OLD }}$ is interpreted as a possibility distribution on possible birth dates (Zadeh).
- Nested intervals $\mathrm{E}_{1}, \mathrm{E}_{2}, \ldots \mathrm{E}_{\mathrm{n}}$ with confidence levels

## POSSIBILITY AND NECESSITY OF AN EVENT

How confident are we that $\mathrm{x} \in \mathrm{A} \subset \mathrm{S}$ ? (an event $A$ occurs) given a possibility distribution on $S$

- $\quad \Pi(\mathrm{A})=\max _{\mathrm{s} \in \mathrm{A}} \pi(\mathrm{s})$ :
to what extent A is consistent with $\pi$
( $=$ some $\mathrm{x} \in \mathrm{A}$ is possible)
The degree of possibility that $x \in A$
- $\mathrm{N}(\mathrm{A})=1-\Pi\left(\mathrm{A}^{\mathrm{c}}\right)=\min _{\mathrm{s} \notin \mathrm{A}} 1-\pi(\mathrm{s})$ :
to what extent no element outside A is possible $=$ to what extent $\pi$ implies A

The degree of certainty (necessity) that $\mathrm{x} \in \mathrm{A}$

## Basic properties (finite case)

$$
\begin{gathered}
\Pi(A \cup B)=\max (\Pi(A), \Pi(B)) ; \\
N(A \cap B)=\min (N(A), N(B))
\end{gathered}
$$

Mind that most of the time :
$\Pi(\mathrm{A} \cap \mathrm{B})<\min (\Pi(\mathrm{A}), \Pi(\mathrm{B})) ;$
$\mathrm{N}(\mathrm{A} \cup \mathrm{B})>\max (\mathrm{N}(\mathrm{A}), \mathrm{N}(\mathrm{B})$
Example: Total ignorance on A and $\mathrm{B}=\mathrm{A}^{\mathrm{c}}$

$$
\left(\Pi(\mathrm{A})=\Pi\left(\mathrm{A}^{\mathrm{c}}\right)=1\right)
$$

Corollary $\mathrm{N}(\mathrm{A})>0 \Rightarrow \Pi(\mathrm{~A})=1$

## Comparing information states

- $\pi^{\prime}$ more specific than $\pi$ in the wide sense
if and only if $\pi^{\prime} \leq \pi$
Any possible value according to $\pi^{\prime}$ is at least according to $\pi$ :
$\pi^{\prime}$ is more informative than $\pi$
- COMPLETE KNOWLEDGE: The most specific ones
- $\pi\left(\mathrm{s}_{0}\right)=1 ; \quad \pi(\mathrm{s})=0$ otherwise
- IGNORANCE: $\pi(\mathrm{s})=1, \forall \mathrm{~s} \in \mathrm{~S}$
- Principle of least commitment (minimal specificity): In a given information state, any value not proved impossible is supposed to be possible : maximise possibility degrees.

## Certainty-qualification

- Attaching a degree of certainty $\alpha$ to event A
- It means $N(A) \geq \alpha \Leftrightarrow \Pi\left(A^{c}\right)=\sup _{s \notin A} \pi(\mathrm{~s}) \leq 1-\alpha$
- The least informative $\pi$ sanctioning $\mathrm{N}(\mathrm{A}) \geq \alpha$ is :
$-\pi(\mathrm{s})=1$ if $\mathrm{s} \in \mathrm{A}$ and $1-\alpha$ if $\mathrm{s} \notin \mathrm{A}$
- In other words: $\pi(\mathrm{s})=\max \left(\mu_{\mathrm{A}}, 1-\alpha\right)$

At the limit with an infinity of nested intervals
$\mathrm{N}\left(\mathrm{A}_{\alpha}\right) \geq 1-\alpha, \alpha$ in $(0,1]$

FUZZY INTERVAL

## A pioneer of possibility theory

- In the 1950's, G.L.S. Shackle called "degree of potential surprize" of an event its degree of impossibility = $1-\Pi(A)$.
- Potential surprize is valued on a disbelief scale, namely a positive interval of the form $\left[0, y^{*}\right]$, where $y^{*}$ denotes the absolute rejection of the event to which it is assigned, and 0 means that nothing opposes to the occurrence of A.
- The degree of surprize of an event is the degree of surprize of its least surprizing realization.
- He introduces a notion of conditional possibility

## Qualitative vs. quantitative possibility theories

- Qualitative:
- comparative: A complete pre-ordering $\geq_{\pi}$ on $S$ A wellordered partition of $\mathrm{S}: \mathrm{E} 1>\mathrm{E} 2>\ldots>\mathrm{En}$
- absolute: $\pi_{\mathrm{x}}(\mathrm{s}) \in \mathrm{L}=$ finite chain, complete lattice...
- Quantitative: $\pi_{x}(s) \in[0,1]$, integers...

One must indicate where the numbers come from.

All theories agree on the fundamental maxitivity axiom

$$
\Pi(\mathrm{A} \cup \mathrm{~B})=\max (\Pi(\mathrm{A}), \Pi(\mathrm{B}))
$$

Theories diverge on the conditioning operation

## Quantitative possibility theory

- Membership functions of fuzzy sets
- Natural language descriptions pertaining to numerical universes (fuzzy numbers)
- Results of fuzzy clustering

Semantics: metrics, proximity to prototypes

- Imprecise probability
- Random experiments with imprecise nested outcomes
- Possibility distributions encode special convex probability sets

Semantics: frequentist, or subjectivist (gambles)...

## Blending intervals and probability

- Representations that refine Boolean possibility theory and account for both variability and incomplete knowledge must combine probability and sets.
- Sets of probabilities : imprecise probability theory
- Random(ised) sets : Dempster-Shafer theory
- Fuzzy sets: numerical possibility theory
- Each event has a degree of belief (certainty) and a degree of plausibility, instead of a single degree of probability

## GRADUAL REPRESENTATIONS OF UNCERTAINTY using capacities

## Family of propositions or events $\boldsymbol{E}$ forming a

 Boolean Algebra$-S, \varnothing$ are events that are certain and ever impossible respectively.

- A confidence measure g: a function from $\boldsymbol{E}$ to $[0,1]$ such that
$-g(\emptyset)=0 \quad ; \quad g(S)=1$
- monotony $:$ if $\mathrm{A} \subseteq \mathrm{B}(=\mathrm{A}$ implies B$)$ then $\mathrm{g}(\mathrm{A}) \leq \mathrm{g}(\mathrm{B})$
- $g(A)$ quantifies the confidence of an agent in proposition A.
- g is a Choquet capacity

## BASIC PROPERTIES OF CONFIDENCE MEASURES

- $g(A \cup B) \geq \max (\mathbf{g}(\mathbf{A}), \mathbf{g}(\mathbf{B}))$;
- $\mathbf{g}(\mathbf{A} \cap \mathbf{B}) \leq \min (\mathbf{g}(\mathbf{A}), \mathrm{g}(\mathrm{B}))$
- It includes:
- probability measures: $\mathrm{P}(\mathrm{A} \cup \mathrm{B})=\mathrm{P}(\mathrm{A})+\mathrm{P}(\mathrm{B})-\mathrm{P}(\mathrm{A} \cap \mathrm{B})$
- possibility measures $\Pi(A \cup B)=\max (\Pi(A), \Pi(B))$
- necessity measures $\quad \mathrm{N}(\mathrm{A} \cap \mathrm{B})=\min (\mathrm{N}(\mathrm{A}), \mathrm{N}(\mathrm{B}))$
- The two latter functions do not require a numerical setting

## A GENERAL SETTING FOR REPRESENTING GRADED CERTAINTY AND PLAUSIBILITY

- 2 conjugate set-functions Pl and Cr generalizing probability P , possibility $\Pi$, and necessity N .
- Conventions :
$-\operatorname{Pl}(\mathrm{A})=0$ "impossible" ; Cr(A) = 1 "certain"
$-\operatorname{Pl}(\mathrm{A})=1 ; \operatorname{Cr}(\mathrm{A})=0 \quad$ "ignorance" (no information)
$-\mathrm{Pl}(\mathrm{A})-\mathrm{Cr}(\mathrm{A})$ quantifies ignorance about A
- Postulates
- Cr and Pl are monotonic under inclusion (= capacities).
$-\mathrm{Cr}(\mathrm{A}) \leq \mathrm{Pl}(\mathrm{A})$ "certain implies plausible"
$-\mathrm{Pl}(\mathrm{A})=1-\operatorname{Cr}\left(\mathrm{A}^{\mathrm{c}}\right) \quad$ duality certain/plausible
- If $\mathrm{Pl}=\mathrm{Cr}$ then it is P .

## Imprecise probability theory

- A state of information is represented by a family $P$ of probability distributions over a set X.
- For instance: incomplete knowledge of a frequentist probabilistic model : $\exists P \in \mathcal{P}$.
- To each event A is attached a probability interval $\left[\mathrm{P}_{*}(\mathrm{~A}), \mathrm{P}^{*}(\mathrm{~A})\right]$ such that

$$
\begin{aligned}
& -P_{*}(A)=\inf \{P(A), P \in \mathcal{P}\} \\
& -P^{*}(A)=\sup \{P(A), P \in P\}=1-P_{*}\left(A^{c}\right)
\end{aligned}
$$

- Usually $P$ is strictly contained in $\left\{P(A), P \geq P_{*}\right\}$
- $\left\{\mathrm{P}(\mathrm{A}), \mathrm{P} \geq \mathrm{P}_{*}\right\}$ is convex (credal set).

## WHY REPRESENTING INFORMATION BY PROBABILITY FAMILIES ?

Often probabilistic information is incomplete:

- Expert opinion (fractiles, intervals with confidence levels)
- Subjective estimates of support, mode, etc. of a distribution
- Parametric model with incomplete information on parameters (partial subjective information on mean and variance)
- Parametric model with confidence intervals on parameters due to a small number of observations

## WHY REPRESENTING INFORMATION BY PROBABILITY FAMILIES ?

- In the case of generic (frequentist) information using a family of probabilistic models, rather than selecting a single one, enables to account for incompleteness and variability.
- In the case of subjective belief: distinction between
- not believing a proposition $\left(\mathrm{P}_{*}(\mathrm{~A})\right.$ and $\mathrm{P}_{*}\left(\mathrm{~A}^{\mathrm{c}}\right)$ low)
- and believing its negation $\left(\mathrm{P}_{*}\left(\mathrm{~A}^{\mathrm{c}}\right)\right.$ high $)$.

## Subjectivist view (Peter Walley)

- A theory that handles convex probability sets
$-\mathrm{P}_{\text {low }}(\mathrm{A})$ is the highest acceptable price for buying a bet on singular event A winning 1 euro if A occurs
$-\mathrm{P}^{\text {high }}(\mathrm{A})=1-\mathrm{P}_{\text {low }}\left(\mathrm{A}^{\mathrm{c}}\right)$ is the least acceptable price for selling this bet.
- These prices may differ (no exchangeable bets)
- Rationality conditions:
- No sure loss : $\left\{\mathrm{P} \geq \mathrm{P}_{\text {low }}\right\}$ not empty
- Coherence: $\mathrm{P}_{*}(\mathrm{~A})=\inf \left\{\mathrm{P}(\mathrm{A}), \mathrm{P} \geq \mathrm{P}_{\text {low }}\right\}=\mathrm{P}_{\text {low }}(\mathrm{A})$
- Convex probability sets (credal sets) are actually characterized by lower expectations of real-valued functions (gambles), not just events.

## Capacity-based lower probabilities

- Coherent lower probabilities are important examples of certainty functions. The most general numerical approach to uncertainty : $C r=P_{*}$
- They satisfy super-additivity: if $\mathrm{A} \cap \mathrm{B}=\varnothing$ then

$$
\mathrm{P}_{*}(\mathrm{~A})+\mathrm{P}_{*}(\mathrm{~B}) \leq \mathrm{P}_{*}(\mathrm{~A} \cup \mathrm{~B})
$$

- One may require the 2-monotony property for Cr :
$\mathrm{Cr}(\mathrm{A})+\mathrm{Cr}(\mathrm{B}) \leq \mathrm{Cr}(\mathrm{A} \cup \mathrm{B})+\mathrm{Cr}(\mathrm{A} \cap \mathrm{B})$
- ensures non-empty coherent credal set:

$$
\mathcal{P}(\mathrm{Cr})=\{\mathrm{P}: \mathrm{P}(\mathrm{~A}) \geq \mathrm{Cr}(\mathrm{~A})\} \neq \emptyset .
$$

Cr is then called a convex capacity.

## Coherence and deductive closure

- Suppose the knowledge is of the form of a consistent set $\mathcal{B}$ of assertions $\phi_{i}$ of the form

$$
\text { « } \mathrm{x} \text { in } \mathrm{E}_{\mathrm{i}} » \mathrm{i}=1, \ldots, \mathrm{n} \quad\left(\text { interpreted as } \mathrm{N}\left(\mathrm{E}_{\mathrm{i}}\right)=1\right)
$$

- The set of consequences of $B=\left\{\phi_{i} i=1, \ldots, n\right\}$ is $C(\mathcal{B})=\{\phi|\mathcal{B}|=\phi\}$ (deductively closed)
- Define a Boolean necessity function $\mathrm{N}^{*}$ such that $\mathrm{N}^{*}(\mathrm{~A})=1$ iff $\phi=《 \mathrm{x}$ in A » in $C(\mathcal{B})$ iff $\mathrm{E}=\cap_{\mathrm{i}=1, \ldots, \mathrm{n}} \mathrm{E}_{\mathrm{i}} \subseteq \mathrm{A}$

## Coherence and deductive closure

- If the knowledge $\mathcal{B}$ is viewed as the credal set $\left\{\mathrm{P}: \mathrm{P}\left(\mathrm{E}_{\mathrm{i}}\right)=1, \mathrm{i}=1, \ldots, \mathrm{n}\right\}$ then the coherent lower probability induced by its natural extension is the Boolean necessity function $\mathrm{N}^{*}$, obtained from the deductive closure $C(\mathcal{B})$, which is another example of coherent lower probability.
- Conclusion Coherence generalizes deductive closure, and a consequence of B is a formula whose set of models has lower probability 1 .

## Random sets

- A probability distribution $m$ on the family of non-empty subsets of a set $S$.
- A positive weighting of non-empty subsets: mathematically, a random set :

$$
\sum_{\mathrm{E} \in \mathcal{F}} \mathrm{~m}(\mathrm{E})=1
$$

- m : mass function.
- focal sets $: \mathrm{E} \in \mathcal{F}$ with $\mathrm{m}(\mathrm{E})>0$.

## Disjunctive random sets

- $\mathrm{m}(\mathrm{E})=$ probability that the most precise description of the available information is of the form "x $\in \mathrm{E}$ " for epistemic set E .
It is the probability of [only knowing " $x \in E$ " and nothing else]
- It is the portion of probability mass hanging over elements of E without being allocated.
- DO NOT MIX UP m(E) and P(E)

## Basic set functions from random sets

- degree of certainty (belief) :
$-\operatorname{Bel}(A)=\sum \quad m\left(E_{i}\right)$

$$
\mathrm{E}_{\mathrm{i}} \subseteq \mathrm{~A}, \mathrm{E}_{\mathrm{i}} \neq \emptyset
$$

- total mass of information implying the occurrence of A
- (probability of provability)
- degree of plausibility :
$-\mathrm{Pl}(\mathrm{A})=\sum \quad \mathrm{m}\left(\mathrm{E}_{\mathrm{i}}\right)=1-\operatorname{Bel}\left(\mathrm{A}^{\mathrm{c}}\right) \geq \operatorname{Bel}(\mathrm{A})$

$$
\mathrm{E}_{\mathrm{i}} \cap \mathrm{~A} \neq \emptyset
$$

- total mass of information consistent with A
- (probability of consistency)

Example : $\operatorname{Bel}(\mathrm{A})=\mathrm{m}(\mathrm{E} 1)+\mathrm{m}(\mathrm{E} 2)$

$$
\begin{gathered}
\mathrm{Pl}(\mathrm{~A})=\mathrm{m}(\mathrm{E} 1)+\mathrm{m}(\mathrm{E} 2)+\mathrm{m}(\mathrm{E} 3)+\mathrm{m}(\mathrm{E} 4) \\
=1-\mathrm{m}(\mathrm{E} 5)=1-\mathrm{Bel}\left(\mathrm{~A}^{\mathrm{c}}\right)
\end{gathered}
$$

## Random disjunctive sets vs. imprecise probabilities

- The set $\boldsymbol{P}_{\text {bel }}=\{\mathrm{P} \geq \mathrm{Bel}\}$ is coherent: Bel is a special case of lower probability
- Bel is $\infty$-monotone (super-modular at any order)
- Order 3: $\operatorname{Bel}(\mathrm{A} \cup \mathrm{B} \cup \mathrm{C}) \geq \operatorname{Bel}(\mathrm{A})+\mathrm{Bel}(\mathrm{B})+\operatorname{Bel}(\mathrm{C})-$ $\operatorname{Bel}(\mathrm{A} \cap \mathrm{B})-\operatorname{Bel}(\mathrm{A} \cap \mathrm{C})-\operatorname{Bel}(\mathrm{B} \cap \mathrm{C})+\operatorname{Bel}(\mathrm{A} \cap \mathrm{B} \cap \mathrm{C})$, etc.
- For any set function, the solution $m$ to the set of equations $\forall \mathrm{A} \subseteq \mathrm{Xg}(\mathrm{A})=\sum \quad \mathrm{m}\left(\mathrm{E}_{\mathrm{i}}\right)$

$$
\mathrm{E}_{\mathrm{i}} \subseteq \mathrm{~A}, \mathrm{E}_{\mathrm{i}} \neq \emptyset
$$

is unique (Moebius transform)

- However mis positive iff $g$ is a belief function

## PARTICULAR CASES

- INCOMPLETE INFORMATION:

$$
\mathrm{m}(\mathrm{E})=1, \mathrm{~m}(\mathrm{~A})=0, \mathrm{~A} \neq \mathrm{E}
$$

- TOTAL IGNORANCE $: \mathrm{m}(\mathrm{S})=1$ :
- For all $A \neq \mathrm{S}, \emptyset, \operatorname{Bel}(A)=0, P l(A)=1$
- PROBABILITY: if $\forall \mathrm{i}, \mathrm{E}_{\mathrm{i}}=$ singleton $\left\{\mathrm{s}_{\mathrm{i}}\right\}$ (hence disjoint focal sets )
- Then, for all $\mathrm{A}, \operatorname{Bel}(\mathrm{A})=\operatorname{Pl}(\mathrm{A})=\mathrm{P}(\mathrm{A})$
- Hence precise + scattered information
- POSSIBILITY THEORY : the opposite case $\mathrm{E}_{1} \subseteq \mathrm{E}_{2} \subseteq \mathrm{E}_{3} \ldots \subseteq \mathrm{E}_{\mathrm{n}}:$ imprecise and coherent information
- iff $\operatorname{Pl}(\mathrm{A} \cup \mathrm{B})=\max (\mathrm{Pl}(\mathrm{A}), \mathrm{Pl}(\mathrm{B}))$, possibility measure
- iff $\operatorname{Bel}(A \cap B)=\min (\operatorname{Bel}(A), \operatorname{Bel}(B))$, necessity measure

## From possibility to random sets

- Given $\pi$, construct a basic probability assignment (SHAFER) let $m_{i}=\alpha_{i}-\alpha_{i+1} \quad$ then $m_{1}+\ldots+m_{n}=1$, with focal sets $=$ cuts $A_{i}=\left\{s, \pi(s) \geq \alpha_{i}\right\}$

$$
\operatorname{Bel}(A)=\sum_{\mathrm{Ai} \subseteq \mathrm{~A}} \mathrm{~m}_{\mathrm{i}}=N(A) ; P l(A)=\Pi(A)
$$

- Conversely, $\pi(\mathrm{s})=\sum_{\mathrm{i}: ~} \in \mathrm{Aii}_{\mathrm{i}}$ (one point-coverage function)

$$
=\operatorname{Pl}(\{\mathrm{s}\}) .
$$

- Only in the consonant case can mbe recalculated from $\pi$

## Canonical examples

- Objectivist : Frequentist modelling of a collection of incomplete observations (imprecise statistics) :
- Uncertain subjective information:
- Unreliable testimonies (Shafer's book) : humanoriginated singular information
- Unreliable sensors : the quality/precision of the information depends on the ill-known sensor state.

## Random sets as epistemic sets of random variables

- Dempster model : Indirect information (induced from a probability space).
- All we know about a random variable x with range S , based on a sample space $(\Omega, A, \mathrm{P})$ is based on a multimapping $\Gamma$ from $\Omega$ to $S$ (Dempster):
- The meaning of the multimapping $\Gamma$ from $\Omega$ to $S$ :
- if we observe $\omega$ in $\Omega$ then all we know is $x(\omega) \in \Gamma(\omega)$

$$
\begin{gathered}
\mathrm{m}(\mathrm{E})=\sum\{\mathrm{P}(\{\omega\}): \mathrm{E}=\Gamma(\omega)\} \quad \forall \omega \text { in } \Omega \\
\text { (finite case.) }
\end{gathered}
$$

## Consult for more

- Random Sets and Random Fuzzy Sets as Ill-Perceived Random Variables
An Introduction for Ph.D. Student and Practitioners By Inés Couso, Didier Dubois, Luciano Sanchez SpringerBriefs in Applied Sciences and Technology, 2014
- Inés Couso, Didier Dubois, Statistical Reasoning with Set-Valued Information: Ontic vs. Epistemic Views. Int. J. Approximate Reasoning, 2014

## Example of statistical belief function: imprecise observations in an opinion poll

- Question : who is your preferred candidate

$$
\text { in } C=\{\mathrm{a}, \mathrm{~b}, \mathrm{c}, \mathrm{~d}, \mathrm{e}, \mathrm{f}\} ? ? ?
$$

- To a population $\Omega=\{1, \ldots, i, \ldots, n\}$ of $n$ persons.
- Imprecise responses $\mathbf{r}=« x(i) \in \mathrm{E}_{\mathrm{i}} »$ are allowed
- No opinion ( $\mathrm{r}=\mathrm{C}$ ) ; «left wing» $\mathrm{r}=\{\mathrm{a}, \mathrm{b}, \mathrm{c}\}$;
- «right wing »r=\{d,e,f\};
- a moderate candidate : $\mathrm{r}=\{\mathrm{c}, \mathrm{d}\}$
- Definition of mass function:
$-m(E)=\operatorname{card}\left(\left\{i, E_{i}=E\right\}\right)_{n}$
- = Proportion of imprecise responses $« x(i) \in E »$
- The probability that a candidate in subset $A \subseteq C$ is elected is imprecise :

$$
\operatorname{Bel}(\mathrm{A}) \leq \mathrm{P}(\mathrm{~A}) \leq \mathrm{Pl}(\mathrm{~A})
$$

- There is a fuzzy set $\mathbf{F}$ of potential winners:

$$
\mu_{\mathrm{F}}(\mathrm{x})=\sum_{\mathrm{x} \in \mathrm{E}} \mathrm{~m}(\mathrm{E})=\operatorname{Pl}(\{\mathrm{x}\}) \text { (contour function) }
$$

- $\mu_{\mathrm{F}}(\mathrm{x})$ is an upper bound of the probability that x is elected. It gathers responses of those who did not give up voting for x
- $\operatorname{Bel}(\{x\})$ gathers responses of those who claim they will vote for x and no one else.

## Example of uncertain evidence : Unreliable testimony (SHAFER-SMETS VIEW)

- «John tells me the president is between 60 and 70 years old, but there is some chance (subjective probability p) he does not know and makes it up».
$-\mathrm{E}=[60,70]$; $\operatorname{Prob}($ Knowing $" \mathrm{x} \in \mathrm{E}=[60,70] ")=1-\mathrm{p}$.
- With probability p, John invents the info, so we know nothing
(Note that this is different from a lie).
- We get a simple support belief function :

$$
m(E)=1-p \quad \text { and } \quad m(S)=p
$$

- Equivalent to a possibility distribution

$$
-\pi(s)=1 \text { if } x \in E \quad \text { and } \quad \pi(s)=p \text { otherwise }
$$

## Unreliable testimony with lies

- «John tells me the president is between 60 and 70 years old, but
- there is some chance (subjective probability p ) he does not know and makes it up».
- John may lie (probability q):
- $\mathrm{E}=[60,70]$
- Modeling
- John is competent and does not lie : $m(E)=(1-p)(1-q)$,
- John is competent and lies $m\left(E^{c}\right)=(1-p) q$.
- John is incompetent and is boasting : $\mathrm{m}(\mathrm{S})=\mathrm{p}$

## Dempster vs. Shafer-Smets

- A disjunctive random set can represent
- Uncertain singular evidence (unreliable testimonies): $m(E)=$ subjective probability pertaining to the truth of testimony E .
- Degrees of belief directly modelled by Bel : no appeal to an underlying probability.
(Shafer, 1976 book; Smets)
- Imprecise statistical evidence: $\mathrm{m}(\mathrm{E})=$ frequency of imprecise observations of the form E and $\operatorname{Bel}(\mathrm{E})$ is a lower probability
- A multiple-valued mapping from a probability space to a space of interest representing an ill-known random variable.
- Here, belief functions are explicitly viewed as lower probabilities
(Dempster intuition)
- In all cases $E$ is a set of mutually exclusive values and does not represent a real set-valued entity

## Example of conjunctive random sets

## Experiment on linguistic capabilities of people :

- Question to a population $\Omega=\{1, \ldots, \mathrm{i}, \ldots, \mathrm{n}\}$ of n persons: which languages can you speak ?
- Answers : Subsets in $\mathcal{L}=\{$ Basque, Chinese, Dutch, English, French,....\} ?
- $\mathrm{m}(\mathrm{E})=$ \% people who speak exactly all languages in E (and not other ones)
- $\operatorname{Prob}(x$ speaks $A)=\sum\{m(E): A \subseteq E\}=Q(A):$ commonality function in belief function theory
- Example: «x speaks English » means « at least English »
- The belief function is not meaningful here while the commonality makes sense, contrary to the disjunctive set case.

## POSSIBILITY AS UPPER PROBABILITY

- Given a numerical possibility distribution $\pi$, define $P(\pi)=\{P \mid P(A) \leq \Pi(A)$ for all $A\}$
- Then, generally it holds that

$$
\begin{aligned}
& \Pi(\mathrm{A})=\sup \{\mathrm{P}(\mathrm{~A}) \mid \mathrm{P} \in \mathcal{P}(\pi)\} ; \\
& \mathrm{N}(\mathrm{~A})=\inf \{\mathrm{P}(\mathrm{~A}) \mid \mathrm{P} \in \mathcal{P}(\pi)\}
\end{aligned}
$$

- So N and P are special cases of coherent lower and upper probabilities
- So $\pi$ is a very simple representation of a credal set (convex family of probability measures)

## LIKELIHOOD FUNCTIONS

- Likelihood functions $\lambda(x)=P(A \mid x)$ behave like possibility distributions when there is no prior on x , and $\lambda(\mathrm{x})$ is used as the likekihood of $x$.
- It holds that $\lambda(\mathrm{B})=\mathrm{P}(\mathrm{Al} \mathrm{B}) \leq \max _{\mathrm{x} \in \mathrm{B}} \mathrm{P}(\mathrm{Al} \mathrm{x})$
- If $P(A \mid B)=\lambda(B)$ is the likelihood of " $x \in B$ " then $\lambda$ should be a capacity (monotonic with inclusion):

$$
\{\mathrm{x}\} \subseteq \mathrm{B} \text { implies } \lambda(\mathrm{x}) \leq \lambda(\mathrm{B})
$$

It implies $\lambda(B)=\max _{x \in B} \lambda(\mathbf{x})$ if no prior probability is available for x .

## Maximum likelihood principle is possibility theory

- The classical coin example: $\theta$ is the unknown probability of "heads"
- Within n experiments: k heads, n - k tails
- $\mathrm{P}(\mathrm{k}$ heads, $\mathrm{n}-\mathrm{k}$ tails $\mid \theta)=\theta^{\mathrm{k} \cdot}(1-\theta)^{\mathrm{nk}}$ is the degree of possibility $\pi(\theta)$ that the probability of "head" is $\theta$.
In the absence of other information the best choice is the one that maximizes $\pi(\theta), \theta \in[0,1]$

It yields $\theta=\mathrm{k} / \mathrm{n}$.

## LANDSCAPE OF UNCERTAINTY THEORIES

BAYESIAN/STATISTICAL PROBABILITY: the language of unique probability distributions (Randomized points)

UPPER-LOWER PROBABILITIES : the language of disjunctive convex sets of probabilities, and lower expectations
SHAFER-SMETS BELIEF FUNCTIONS: The language of
Moebius masses (Random disjunctive sets)
QUANTITATIVE POSSIBILITY THEORY: The language of possibility distributions (Fuzzy (nested disjunctive) sets)

BOOLEAN POSSIBILITY THEORY (modal logic KD) :
The language of Disjunctive sets

## Language difficulties

- Imprecise probability, belief functions and possibility theory are in fact not fully mutually consistent:
- Concepts that make sense for credal sets, may be hard to interpret in terms of Moebius transforms or possibility distributions and conversely
- Simplified representations help us cut down computation costs (possibility distributions and simple belief functions)

## Practical representations

- Fuzzy intervals
- Probability intervals
- Probability boxes
- Generalized p-boxes
- Clouds

Some are special random sets some not.

## Probability intervals (De Campos, Moral)

- Probability intervals $=$ a finite collection L of imprecise assignments $\left[l_{i}, u_{i}\right]$ attached to elements $s_{i}$ of a finite set S.
- A collection $L=\left\{\left[l_{i}, u_{i}\right] i=1, \ldots n\right\}$ induces the family $\mathcal{P}_{L}$ $=\left\{P: l_{i} \leq P\left(\left\{s_{i}\right\}^{\prime}\right) \leq u_{i}\right\}$.
- A probability interval model L is coherent in the sense of Walley if and only if

$$
-\sum_{j \neq i} l_{j}+u_{i} \leq 1 \text { and } 1 \leq \sum_{j \neq i} u_{j}+l_{i}
$$

- Lower/upper probabilities on events are given by
$-P_{*}(A)=\max \left(\Sigma_{\text {si } \in \mathrm{A}} l_{i} ; 1-\Sigma_{\text {si申A }} u_{i}\right)$;
$-P^{*}(A)=\min \left(\sum_{\mathrm{si} \in \mathrm{A}} u_{i} ; 1-\Sigma_{\text {si } \notin \mathrm{A}} l_{i}\right)$
- $P_{*}$ is a 2-monotone Choquet capacity (De Campos and Moral)

## From probabilistic confidence sets to possibility distributions

- Let $E_{1}, E_{2}, \ldots E_{n}$ be a nested family of sets
- A set of confidence levels $a_{1}, a_{2}, \ldots a_{n}$ in $[0,1]$
- Consider the set of probabilities

$$
\mathcal{P}=\left\{\mathrm{P}, \mathrm{P}\left(\mathrm{E}_{\mathrm{i}}\right) \geq \mathrm{a}_{\mathrm{i}}, \text { for } \mathrm{i}=1, \ldots \mathrm{n}\right\}
$$

- Then $\mathcal{P}$ is representable by means of a possibility measure with distribution

$$
\pi(\mathrm{x})=\min _{\mathrm{i}=1, \ldots \mathrm{n}} \max \left(\mu_{\mathrm{Ei}}(\mathrm{x}), 1-\mathrm{a}_{\mathrm{i}}\right)
$$

## POSSIBILITY DISTRIBUTION INDUCED BY EXPERT CONFIDENCE INTERVALS

A possibility distribution can be obtained from any family of nested confidence sets and defines the credal set $\left\{\mathrm{P}: \mathrm{P}\left(\mathrm{A}_{\alpha}\right) \geq 1-\alpha, \alpha \in(0,1]\right\}$

FUZZY INTERVAL: $\mathrm{N}\left(\mathrm{A}_{\alpha}\right)=1-\alpha$

## Possibilistic view of probabilistic inequalities

Probabilistic inequalities can be used for knowledge representation:

- Chebyshev inequality defines a possibility distribution that dominates any density with given mean and variance.
- Choosing sets $\left[x^{\text {mean }}-k \sigma, x^{\text {mean }}+k \sigma\right], \mathrm{k}>0$

$$
\begin{gathered}
P\left(V \in\left[x^{\text {mean }}-k \sigma, x^{\text {mean }}+k \sigma\right]\right) \geq 1-1 / k^{2} \\
\text { is equivalent to writing } \\
\pi\left(x^{\text {mean }}-k \sigma\right)=\pi\left(x^{\text {mean }}+k \sigma\right)=1 / k^{2}
\end{gathered}
$$

## Possibilistic view of probabilistic inequalities 2

Probabilistic inequalities can be used for knowledge representation:

- Choosing mode, bounded support $\left[\mathrm{x}_{*}, \mathrm{x}^{*}\right]$ and sets $\mathrm{E}_{\alpha}$ of the form

$$
\left[x^{\text {mode }}-(1-\alpha)\left(x^{\text {mode }}-x_{*}\right), x^{\text {mode }}+(1-\alpha)\left(x^{*}-x^{\text {mode }}\right)\right]
$$

- $P\left(V \in \mathrm{E}_{\alpha}\right) \geq 1-\alpha$ is equivalent to defining a triangular fuzzy interval (TFI)
$\pi\left(x^{\text {mode }}-(1-\alpha)\left(x^{\text {mode }}-x_{*}\right)\right)=\pi\left(x^{\text {mode }}+(1-\alpha)\left(x^{*}-x^{\text {mode }}\right)\right)=\alpha$
A TFN defines a possibility distribution that dominates any unimodal density with the same mode and bounded support as the TFN.

## Optimal order-faithful fuzzy prediction intervals

- The interval $\mathrm{I}_{\mathrm{L}}=\left[\mathrm{a}_{\mathrm{L}}, \mathrm{a}_{\mathrm{L}}+\mathrm{L}\right]$ of fixed length $L$ with maximal probability is of the form $\{x, p(x) \geq \beta\}$
- The most narrow prediction interval with probability $\alpha$ is of the form $\{x, p(x) \geq \beta\}$
- So the most natural (narrow) possibility counterpart of $p$ is

$$
\begin{aligned}
& \pi_{p}\left(a_{L}\right)=\pi_{p}\left(a_{L}+L\right)= \\
& 1-P\left(I_{L}=\{x, p(x) \geq \beta\}\right)
\end{aligned}
$$

Such that $\Pi(A) \geq P(A)$ for all

Optimal order-faithful fuzzy prediction interval

Unimodal and symmetric probability distribution Nested confidence intervals Triangular possibility distribution

## Applications of the prob->pos transform

- Extraction of most narrow confidence of prediction intervals for all confidence levels
- Representing insufficient statistical data by a simple credal set.
- Comparing pdfs according to their dispersions (entropy) :

$$
\pi_{p} \geq \pi_{q} \operatorname{implies} \operatorname{Ent}(p) \leq \operatorname{Ent}(q)
$$

(it works even for densities with infinite variance)

## Probability boxes

- A set $\mathcal{P}=\left\{\mathrm{P}: \mathrm{F}^{*} \geq \mathrm{P} \geq \mathrm{F}_{*}\right\}$ induced by two cumulative disribution functions is called a probability box (p-box),
- A p-box is a special random interval (continuous belief function) whose upper and lower bounds induce the same ordering.

## Probability boxes from possibility distributions

$$
\begin{aligned}
-\quad \mathrm{F}^{*}(\mathrm{a})=\Pi_{\mathrm{M}}((-\infty, \mathrm{a}]) & =\pi(\mathrm{a}) \text { if } \mathrm{a} \leq \mathrm{m} \\
& =1 \text { otherwise. } \\
-\quad \mathrm{F}_{*}(\mathrm{a})=\mathrm{N}_{\mathrm{M}}((-\infty, \mathrm{a}]) & =0 \text { if } \mathrm{a}<\mathrm{m}^{*} \\
& =1-\lim _{\mathrm{x} \downarrow \mathrm{a}} \pi(\mathrm{x}) \text { otherwise }
\end{aligned}
$$

- Representing families of probabilities by fuzzy intervals is more precise than with the corresponding pairs of PDFs: $\mathcal{P}(\pi)$ is a proper subset of $\mathcal{P}=\left\{\mathrm{P}: \mathrm{F}^{*} \geq \mathrm{P} \geq \mathrm{F}_{*}\right\}$
- Not all P in $\mathcal{P}$ are such that $\Pi \geq \mathrm{P}$

## P-boxes vs. fuzzy intervals

A triangular fuzzy number with support [1,3] and mode 2. Let P be defined by $\mathrm{P}(\{1.5\})=\mathrm{P}(\{2.5\})=0.5$.
Then $\mathrm{F}_{*}<\mathrm{F}<\mathrm{FP} \notin \mathrm{P}(\Pi)$ since $\mathrm{P}(\{1.5,2.5\})=1>\Pi(\{1.5,2.5\})=0.5$

## Cumulative distributions

- A Cumulative distribution function $F$ $\mathrm{F}(\mathrm{x})=\mathrm{P}(\{\mathrm{X} \leq \mathrm{x}\})$
of a probability function $P$ can be viewed as a possibility distribution dominating $P$ since the sets
$\{\mathrm{X} \leq \mathrm{x}\}$ are nested
- in particular, $\sup \{\mathrm{F}(\mathrm{x}), \mathrm{x} \in \mathrm{A}\} \geq \mathrm{P}(\mathrm{A})$
- Fuzzy intervals can be viewed as cumulative distribution functions with different kinds of nested sets as $\{X \leq x\}$

## Generalized p-boxes

- Consider nested confidence intervals $\mathrm{E}_{1}, \mathrm{E}_{2}, \ldots \mathrm{E}_{\mathrm{n}}$ each with two probability bounds $\alpha_{\mathrm{i}}$ and $\beta_{\mathrm{i}}$ such that

$$
\mathcal{P}=\left\{\alpha_{\mathrm{i}} \leq \mathrm{P}\left(\mathrm{E}_{\mathrm{i}}\right) \leq \beta_{\mathrm{i}} \text { for } \mathrm{i}=1, \ldots, \mathrm{n}\right\}
$$

- It comes down to two possibility distributions

$$
\pi\left(\text { from } \alpha_{i} \leq \mathrm{P}\left(\mathrm{E}_{\mathrm{i}}\right)\right)
$$

$$
\text { and } \pi_{c}\left(\text { from } P\left(E_{i}^{c}\right) \geq 1-\beta_{i}\right)
$$

- $\pi(\mathrm{x})=\min _{\mathrm{i}=1, \ldots \mathrm{n}} \max \left(\mu_{\mathrm{Ei}}(\mathrm{x}), 1-\alpha_{\mathrm{i}}\right)$
- $\pi_{\mathrm{c}}(\mathrm{x})=\min _{\mathrm{i}=1, \ldots \mathrm{n}} \max \left(1-\mu_{\mathrm{Ei}}(\mathrm{x}), \beta_{\mathrm{i}}\right)$

We get a p-box if $\mathrm{E}_{\mathrm{i}}=\left\{\mathrm{x} \leq \mathrm{a}_{\mathrm{i}}\right\}$

## Generalized p-boxes

- Since $\alpha_{i} \leq \beta_{i}$, distributions $\pi$ and $\pi_{c}$ are such that
$-\pi(x) \geq 1-\pi_{\mathrm{c}}(\mathrm{x})=\delta(\mathrm{x})=\max _{\mathrm{i}=1, \ldots \mathrm{n}} \min \left(\mu_{\mathrm{Ei}}(\mathrm{x}), 1-\beta_{\mathrm{i}}\right)$
- and $\pi$ is comonotonic with $\delta$ (they induce the same order of values $x$ ).

## Credal set : $\mathcal{P}=\mathcal{P}(\pi) \cap \mathcal{P}\left(\pi_{c}\right)$

- Theorem: a generalized p-box is a belief function (random set) with focal sets

$$
\{\mathrm{x}: \pi(\mathrm{x}) \geq \alpha\} \backslash\{\mathrm{x}: \delta(\mathrm{x})>\alpha\}
$$

If $\delta(x)=0$ : usual possibility distribution

$$
\begin{aligned}
& \pi(a)=\pi(b)=1-\alpha \\
& \delta(a)=\delta(b)=1-\beta
\end{aligned}
$$

## Generalized p-box

## Elementary example of a generalized p-box

- All that is known is that $\mathrm{P}(\mathrm{E})$ in $[\mathrm{a}, \mathrm{b}]$ on a finite set E of S
- It corresponds to the belief function:
- $m(E)=a ; m\left(E^{c}\right)=1-b ; m(S)=b-a$.
- The two possibility distributions :
$-\pi(s)=1$ if $s$ in $E ; 1-$ a otherwise.
$-\pi_{c}(s)=1$ if $s$ in $E^{c}$; b otherwise.
- The generalized p-box $\left(\pi_{1}, 1-\pi_{c}\right)$

## From generalized p-boxes to clouds

Fig 1.A Comonotonic cloud

Fig 1.B Non-comonotonic cloud

## How useful are these representations:

- Can help elicitating credal sets from data or experts, and summarizing outputs of an imprecise probability method.
- Usual P-boxes can address questions about threshold violations ( $\mathrm{x} \geq \mathrm{a}$ ??), not questions of the form $\mathrm{a} \leq \mathrm{x} \leq \mathrm{b}$ ??
- The latter questions are better addressed by possibility distributions or generalized p-boxes

## Relationships between representations

- Generalized p-boxes are special random sets that generalize BOTH p-boxes and possibility distributions
- Clouds extend G. P-boxes but induce lower probabilities that are not even 2-monotonic.
- Probability intervals are not comparable to generalized p-boxes: they induce lower probabilities that are 2-monotonic

## Important pending theoretical issues

- Comparing representations in terms of informativeness.
- Conditioning : several definitions for several purposes in the various special cases.
- Independence notions: distinguish between epistemic and objective notions.
- Find a general setting for information fusion operations (e.g. Dempster rule of combination).

## Comparing belief functions in terms of informativeness

- Consonant case : relative specificity.
$\pi$ ' more specific (more informative) than $\pi$ in the wide sense if and only if $\pi^{\prime} \leq \pi$.
(any possible value in information state $\pi^{\prime}$ is at least as possible in information state $\pi$ )
- Complete knowledge: $\pi\left(\mathrm{s}_{0}\right)=1$ and $=0$ otherwise.
- Ignorance: $\pi(s)=1, \forall s \in S$

## Comparing belief functions in terms of informativeness

- 1. Using contour functions:

$$
\pi(\mathrm{s})=\operatorname{Pl}(\{\mathrm{s}\})=\sum_{\mathrm{s} \in \mathrm{E}} \mathrm{~m}(\mathrm{E})
$$

$\mathrm{m}_{1}$ is more cf-informative that $\mathrm{m}_{2}$ iff $\pi_{1} \leq \pi_{2}$

- Corresponds to the specificity ordering in the consonant case
- Degree of imprecision

$$
\left|\mathrm{ml}=\sum_{\mathrm{E}} \mathrm{~m}(\mathrm{E}) *\right| \mathrm{E} \mid=\sum_{\mathrm{s} \in \mathrm{~S}} \pi(\mathrm{~s})
$$

- $\pi_{1} \leq \pi_{2}$ implies $\left|m_{1}\right| \leq\left|m_{2}\right|$

## Comparing belief functions in terms of informativeness

- 2. Using belief or plausibility functions : $\mathrm{m}_{1}$ is more pl-informative that $\mathrm{m}_{2}$ iff $\mathrm{Pl}_{1} \leq \mathrm{Pl}_{2}$ iff $\mathrm{Bel}_{1} \geq \mathrm{Bel}_{2}$
It corresponds to comparing credal sets

$$
P(m)=\{P \geq \operatorname{Bel}\}:
$$

$\mathrm{Pl}_{1} \leq \mathrm{Pl}_{2}$ if and only if $\mathrm{P}\left(\mathrm{m}_{1}\right) \subseteq \mathrm{P}\left(\mathrm{m}_{2}\right)$

## Comparing belief functions in terms of informativeness

- 3. Comparing commonality functions: $\mathrm{m}_{1}$ is more Q -informative that $\mathrm{m}_{2}$ iff

$$
\mathrm{m}_{1} \subseteq_{\mathrm{Q}} \mathrm{~m}_{2} \text { iff } \mathrm{Q}_{1} \leq \mathrm{Q}_{2}
$$

where $\mathrm{Q}(\mathrm{A})=\sum_{\mathrm{A} \mathrm{\subseteq Ei}} \mathrm{~m}\left(\mathrm{E}_{\mathrm{i}}\right)$

- There are larger focal sets for $m_{2}$ than for $\mathrm{m}_{1}$
- A typical information ordering for belief functions.

## Specialisation

- 4. $m_{l}$ is more specialised than $m_{2}$ iff
- Any focal set of $m_{1}$ is included in at least one focal set of $m_{2}$
- Any focal set of $m_{2}$ contains at least one focal set of $m_{1}$
- There is a stochastic matrix W that shares masses of focal sets of $m_{2}$ among focal sets of $\mathrm{m}_{1}$ that contain them:
- $\quad m_{2}(E)=\sum_{\mathrm{F} \subseteq \mathrm{E}} \mathrm{W}(\mathrm{E}, \mathrm{F}) \mathrm{m}_{1}(\mathrm{~F})$

## Results

- $\mathrm{m}_{1} \subseteq_{\mathrm{s}} \mathrm{m}_{2}$ implies $\mathrm{m}_{1} \subseteq_{\mathrm{Pl}} \mathrm{m}_{2}$ implies $\mathrm{m}_{1} \subseteq_{\mathrm{cf}} \mathrm{m}_{2}$
- $\mathrm{m}_{1} \subseteq_{\mathrm{s}} \mathrm{m}_{2}$ implies $\mathrm{m}_{1} \subseteq_{\mathrm{Q}} \mathrm{m}_{2}$ implies $\mathrm{m}_{1} \subseteq_{\mathrm{cf}} \mathrm{m}_{2}$
- However $\mathrm{m}_{1} \subseteq_{\mathrm{PI}} \mathrm{m}_{2}$ and $\mathrm{m}_{1} \subseteq_{\mathrm{Q}} \mathrm{m}_{2}$ are not comparable and can contradict each other
- In the consonant case : all orderings collapse to $\mathrm{m}_{1} \subseteq_{\mathrm{cf}} \mathrm{m}_{2}\left(\pi_{1} \leq \pi_{2}\right)$.

## Example

- $S=\{a, b, c\} ; \mathrm{m}_{1}(\mathrm{ab})=0.5, \mathrm{~m}_{1}(\mathrm{bc})=0.5 ;$
- $\mathrm{m}_{2}(\mathrm{abc})=0.5, \mathrm{~m}_{2}(\mathrm{~b})=0.5$
- $\mathbf{m}_{\mathbf{2}} \subset_{\mathrm{Pl}} \mathbf{m}_{\mathbf{1}}: \mathrm{Pl}_{1}(\mathrm{~A})=\mathrm{Pl}_{2}(\mathrm{~A})$ but $\mathrm{Pl}_{2}(\mathrm{ac})=0.5<\mathrm{Pl}_{1}(\mathrm{ac})=1$
- $\mathbf{m}_{1} \subset_{\mathrm{Q}} \mathbf{m}_{\mathbf{2}}: \mathrm{Q}_{1}(\mathrm{~A})=\mathrm{Q}_{2}(\mathrm{~A})$ but $\mathrm{Q}_{1}(\mathrm{ac})=0<\mathrm{Q}_{2}(\mathrm{ac})=0.5$
- And contour functions are equal : $\mathrm{a} / 0.5, \mathrm{~b} / 1, \mathrm{c} / 0.5$
- Neither $\mathbf{m}_{1} \subseteq_{s} \mathbf{m}_{\mathbf{2}}$ nor $\mathbf{m}_{2} \subseteq_{s} \mathbf{m}_{1}$ holds
- Not comparable \% specialisation

## Next step:

- To be continued with interval data statistics
